

# Deep Brain Stimulation nelle distonie e nella Malattia di Parkinson

Dott. Michele Cavallo

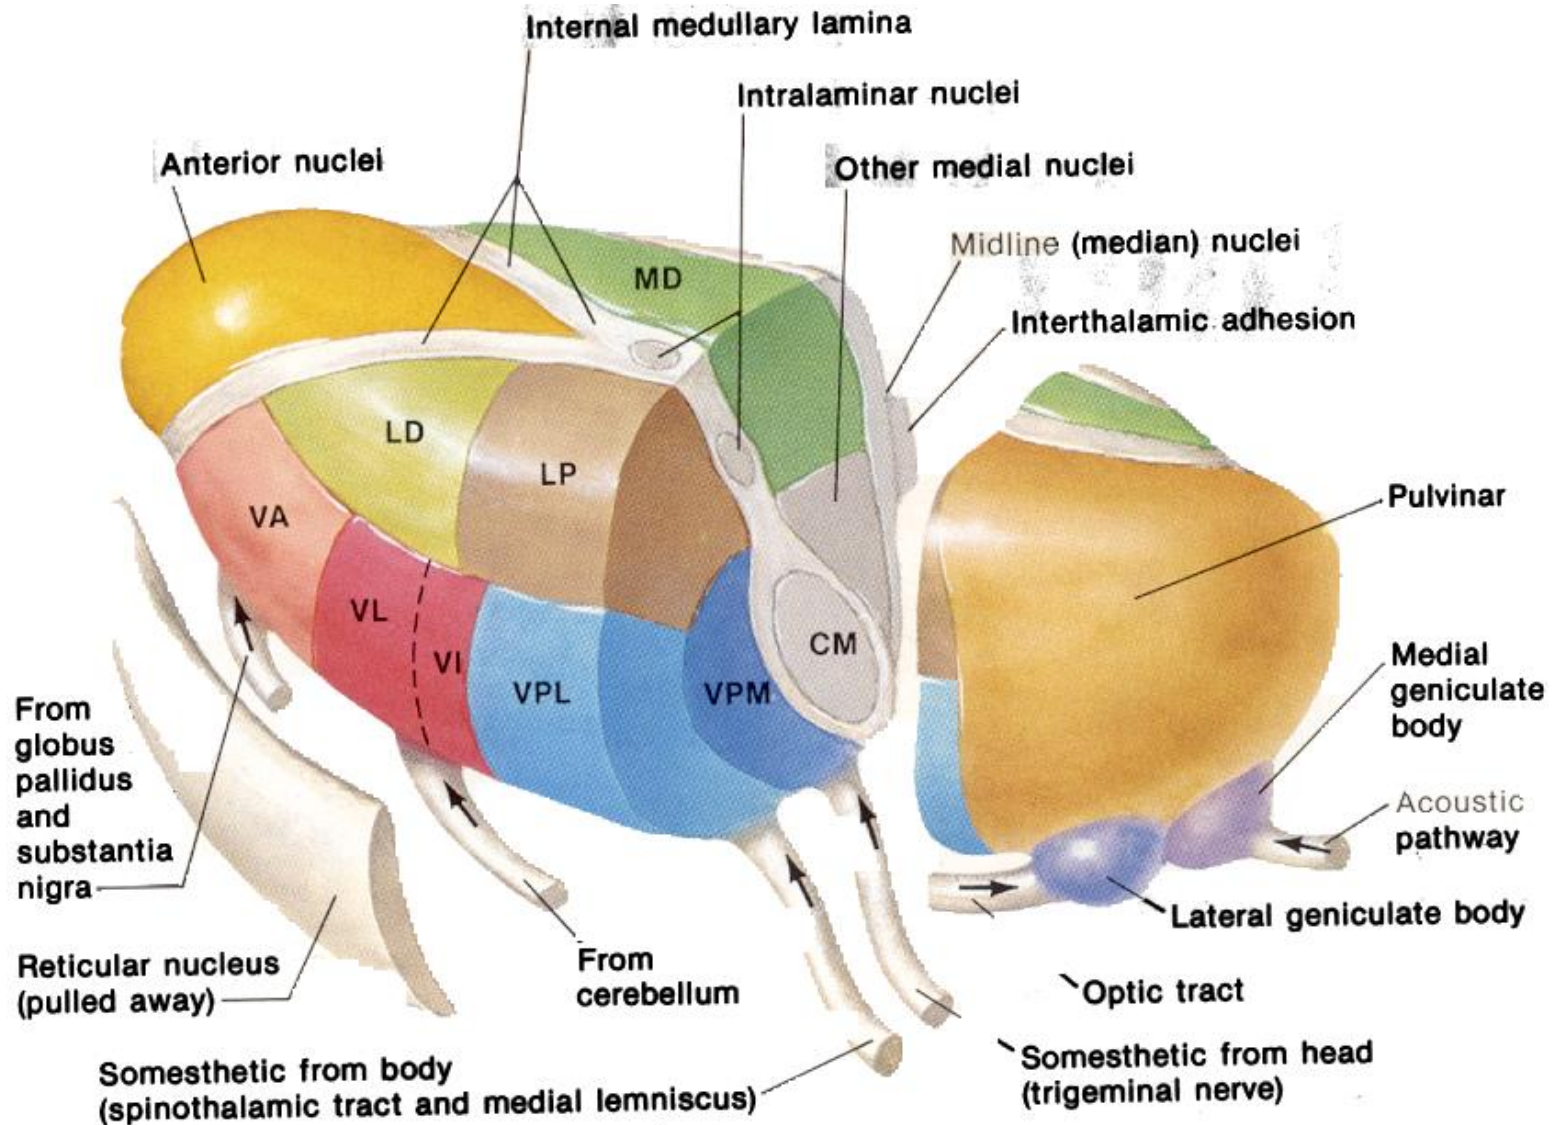

Direttore UO Neurochirurgia

16 Aprile 2015

# Talamo e gangli della base

# Nuclei thalamici

- DBS: nata oltre 25 anni fa, si è dimostrata sicura ed efficace per tremore Essenziale, M. di Parkinson, Distonia
- Successiva estensione delle indicazioni per la DBS a diverse malattie del SNC
- Tratta i sintomi, non la malattia
- Variabilità dei risultati interindividuali
- Variazione nel tempo dell'efficacia/effetti indesiderati

- Progressi nell'identificazione neuroradiologica del target
- Progressi nei sistemi di applicazione degli elettrodi

- Nuove acquisizioni neurofisiologiche sull'attività dei nuclei della base
- Nuovi tipi di stimolazione
- Nuovi sistemi di stimolazione/registrazione
- Nuovi elettrodi

# Indicazioni alla terapia chirurgica

- Malattia di Parkinson idiopatica avanzata
- Grave disabilità
- Perdita di efficacia della terapia farmacologica
- Effetti collaterali da prolungato trattamento con L-dopa
  
- Scale di valutazione della M. di Parkinson:
  - Unified Parkinson Disease Rating Scale (UPDRS)
  - Hoehn-Yahr

# Valutazione funzionale del paziente (UPDRS score)

Paziente \_\_\_\_\_ Data dell'osservazione \_\_\_\_\_

# Indicazione alla DBS

CAPSIT-PD (Core Assessment Program for Surgical Interventional Therapies in PD)

- 1) Parkinson idiopatico (70-30%)
- 2) Assenza di lesioni cerebrali significative
- 3) Età < 70 aa (\*)
- 4) Malattia avanzata e/o SDR da trattamento farmacologico di lungo periodo
- 5) Grado di disabilità: UPDRS dopo 12 h off-terapia
- 6) Buona risposta al test L-Dopa (miglioramento del 50% nella scala UPDRS)
- 7) Assenza di malattie psichiatriche (Valutazione psichiatrica preoperatoria)
- 8) Motivazioni personali/familiari all'intervento
- 9) Assenza di demenze e deficit cognitivi
- 10) Valutazione neuroradiologica preoperatoria
- 11) Valutazione neurochirurgica ed internistica

**Fig. 5.** The STN in the axial plane using SE MRI with image resolution acquired at 44  $\mu\text{m}$  in plane. Panel A just above the level of the STN, Panel B at a superior level of the STN above the RN. The resolution of these images allows clear identification the fibres of the subthalamic fasciculus radiating through the internal capsule.

[Neuroimage. 2012 Feb 1;59\(3\):2035-44. doi: 10.1016/j.neuroimage.2011.10.016. Epub 2011 Oct 21.](#)

**High resolution MR anatomy of the subthalamic nucleus: imaging at 9.4 T with histological validation.**

[Massey LA1](#), [Miranda MA](#), [Zrinzo L](#), [Al-Helli O](#), [Parkes HG](#), [Thornton JS](#), [So PW](#), [White MJ](#), [Mancini L](#), [Strand C](#), [Holton JL](#), [Hariz MI](#), [Lees AJ](#), [Revesz T](#), [Yousry TA](#).

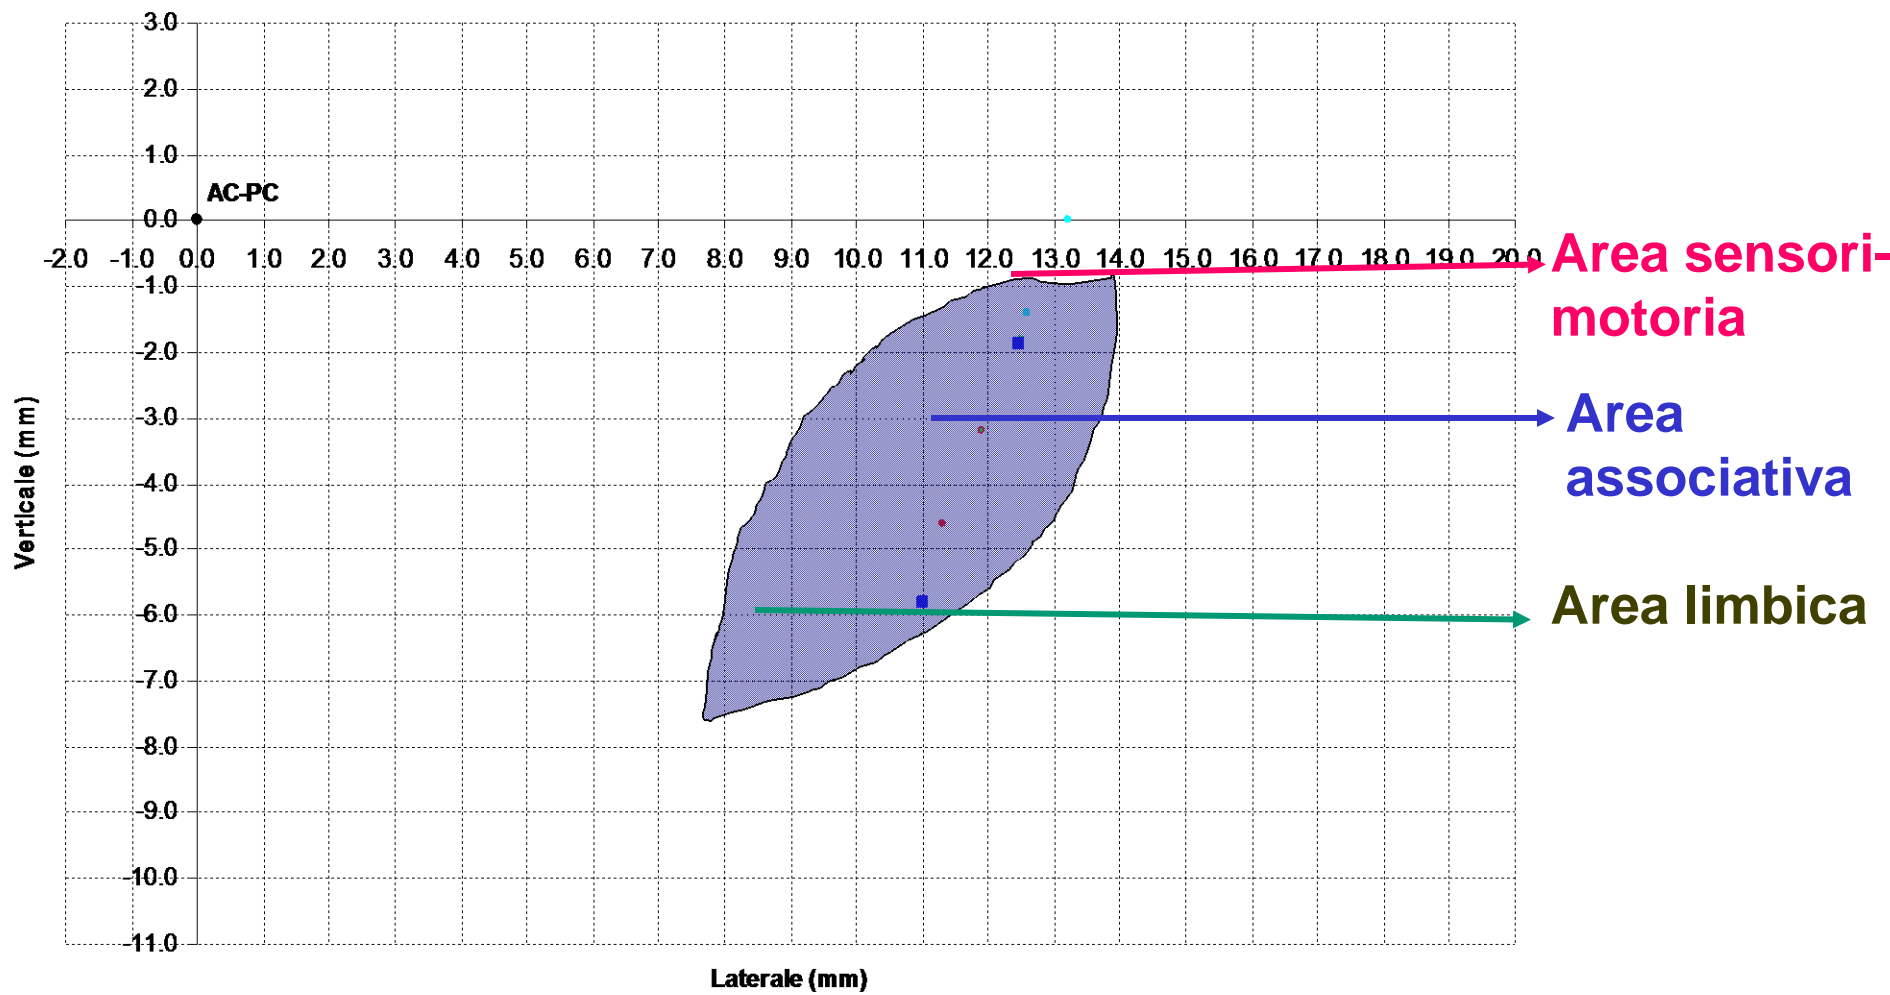

**Fig. 6.** Comparison of 9.4 T SE MRI images [A–D] and histological sections stained using the LFB/CV method [E–H]. MRI in plane resolution 88  $\mu\text{m}$ . Images are unlabelled to make comparison easier. For anatomical labels see Fig. 3. The STN is identified clearly as an almond shaped structure surrounded by white matter tracts (blue stain on LFB/CV images). LFB/CV staining within the STN was uniform in 4/4 cases with no particular anteromedial/posterolateral gradient evident. Structures corresponding to the borders of the STN can be clearly identified: at superior levels the LF can be seen as a dark blue myelinated structure corresponding to a region of hypointensity on T2w images [A and E]. One step inferiorly [B and F] the STN is clearly demarcated by a rim of dark blue staining and the fibres of the subthalamic fasciculus are seen radiating through the internal capsule—corresponding to the hypointensity seen on the anterolateral border of the STN on T2w/PDw images. The posteromedial border is clearly defined on the LFB/CV images as white matter tracts but on the MR images there is a relatively hyperintense signal arising from the region of the zona incerta [B and F]. A region densely staining for myelin is seen separating the STN anteromedially from the superior SN posterolaterally on the LFB/CV image—this corresponds to a relatively hypointense region on the MR image [D and H]. It can be seen that the medial border of the STN is less clearly defined on the LFB/CV image at this level near the posterior aspect of the anteromedial tip on the LFB/CV image but this remains well defined on the 9.4 T SE MR image [H].

**Fig. 2.**

Deterministic diffusion tensor imaging (DTI) used in an individual patient undergoing deep brain stimulation of the subgenual cingulate cortex (SCC) for treatment-resistant major depressive disorder. The DBS site chosen is depicted by the red dot (bottom images), at the nexus of fibers projecting to the ventromedial orbitofrontal cortex, the cingulate bundle, and the nucleus accumbens. (Images courtesy of Helen Mayberg and Patricio Riva Posse, Emory University).

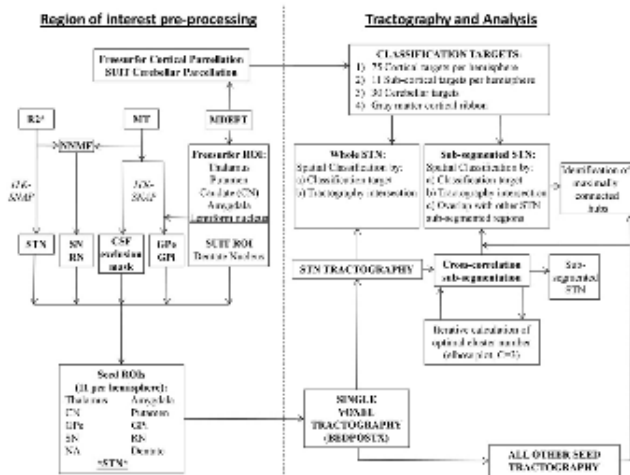

Fig. 1. Methodological pipeline, refer to text for details. Abbreviations: CSF = Cerebrospinal fluid, CN = Caudate nucleus, GPe = External segment of the globus pallidus, GPi = Internal segment of the globus pallidus, MT = Magnetic transfer, NA = Nucleus accumbens, NMMF = Non-negative matrix factorisation, RN = Red nucleus, SN = Substantia nigra, STN = Subthalamic nucleus.

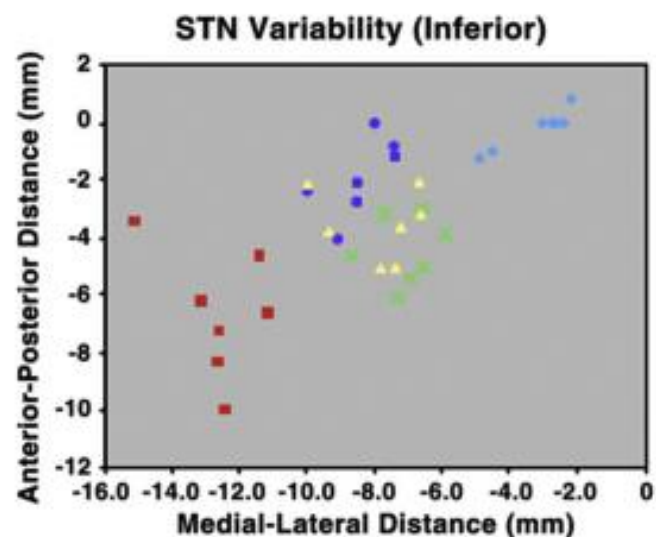

Fig. 6. Overlap of group averaged projections from sub-segmented STN regions. Overlap regions are defined by group averaged tractography distributions in standard space for each STN subregion, and then classifying each ROI brain voxel according to the combination of these average distributions that is connected with it. This is summarised in the top left legend. These demonstrate that the associative regions previously shown (Supplementary Material 2) represent an overlapping network between distinctive motor and limbic networks, sharing regions common to both.

**Fig. 9.** Variability of the position of the STN. Scatter plots on the left include the measured locations of points for all available cases for superior and inferior levels examined. Scatter plots on the right show the mean position relative to the midpoint between the fornix and mamillothalamic tract in the axial plane. The upper and lower 95% confidence intervals are also plotted using coordinates in the x- and y-axis. Points plotted to give the profile of the STN are the medial and lateral tip, the anterior and posterior midpoints and the midpoint of the STN. See Fig. 11. All samples were reoriented such that the midpoint between the MTT and fornix is at position 0 in the x- and y-axis. See Table 3 for mean values and standard deviation.

# Intraoperative MRI DBS

**Fig. 3.**

DBS implantation by direct targeting technique in the intraoperative or interventional MRI scanner: Implantation of globus pallidus internus (GPi) DBS lead(s) using the ClearPoint® SMARTframe (MRI Interventions, Irvine, CA). The skull-mounted targeting cannula is shown in A. Adjustments of pitch/roll and X/Y movements are driven by gears (colored knobs). The entry is determined with respect to a fiducial grid (B, C), and the software determines the point on the grid through which to mark the bone (C). Iterative adjustments are made to the pitch/roll and X/Y using the controller (D) attached to the SMARTFrame, as determined by the software, to align the cannula with the target (E). After final alignment to submillimeter accuracy, an MRI-compatible (i.e. minimal artifact and approved for use in MRI) ceramic stylet is inserted to target through a peel-away catheter. After MR-confirmation of accurate targeting, the stylet is replaced with the DBS lead(s) (F), followed in some centers by a final MRI demonstrating accurate DBS lead position, and finally removal of the peel-away catheter.

**Fig 4.**

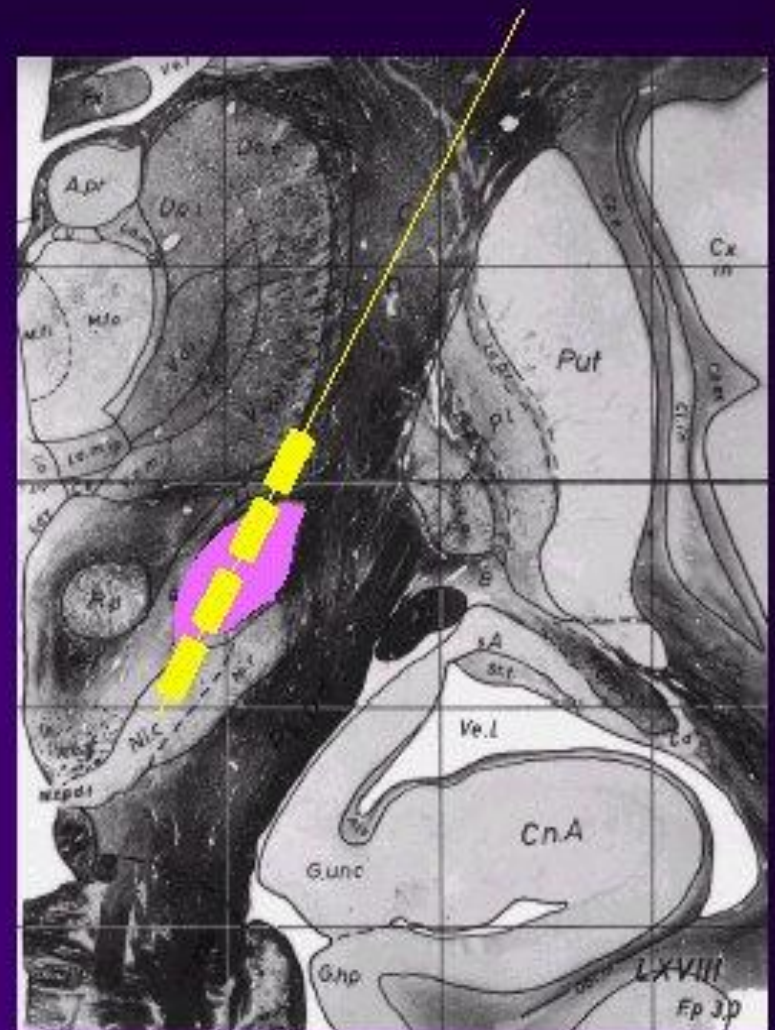

Stereotactic intraoperative CT scanning for 3D radiological control of DBS implantation. Patient positioned within the O-arm® (Medtronic) (A, B). The reference frame for ‘frameless’ navigation is shown (light reflecting off fiducials) to the left of the NexFrame®, a skull-mounted targeting frame with microelectrode inserted (C). The O-arm allows both anterior-posterior (D) and lateral (E) radiography that can be co-registered to the preoperative MRI or CT, using the Stealth® Framelink® navigation workstation (Medtronic). This may be used to track the accuracy of microelectrode insertions, as shown, contributing to the interpretation of neurophysiological recordings. The O-arm also allows 3D CT imaging (F, left), which can be co-registered to the pre-operative imaging (F, right), that can be used for both post-implantation DBS location verification, as well as for bone fiducial registration, allowing the entire procedure (beyond the preoperative MRI scan) to be completed in the operating room. ### **Abstract**

Deep Brain Stimulation (DBS) provides therapeutic benefit for several neuropathologies including Parkinson's disease (PD), epilepsy, chronic pain, and depression. Despite well established clinical efficacy, the mechanism(s) of DBS remains poorly understood. In this review we begin by summarizing the current understanding of the DBS mechanism. Using this knowledge as a framework, we then explore a specific hypothesis regarding DBS of the subthalamic nucleus (STN) for the treatment of PD. This hypothesis states that therapeutic benefit is provided, at least in part, by activation of surviving nigrostriatal dopaminergic neurons, subsequent striatal dopamine release, and resumption of striatal target cell control by dopamine. While highly controversial, we present preliminary data that are consistent with specific predications testing this hypothesis. We additionally propose that developing new technologies, e.g., human electrometer and closed-loop smart devices, for monitoring dopaminergic neurotransmission during STN DBS will further advance this treatment approach.

Fig. 1. Design of a quadripolar DBS lead called "directSTIM" where each electrode pole is divided into three independent compartments that can deliver directionally the electric current in a given direction, so called current-steering. (Reproduced with permission from Aleva Neurotherapeutics SA, Lausanne, Switzerland.)

## Spatial steering of deep brain stimulation volumes using a novel lead design

**Fig. 2.** Non-human primate experiment. (A) Photograph of the acute research version of the DBS-array. (B) The DBS-array was implanted acutely in the left hemisphere along a 20° anterior-posterior angle with the intended target being the globus pallidus. (C) Two sets of four radial electrodes (blue) were examined in terms of local field potentials. (D) The capacity of the DBS-array to deliver directionally-selective stimulation was confirmed by comparing EMG activity during stimulation on either the medial (column A) or lateral (column C) side of the DBS-array. In this case, bipolar stimulation (0.8 mA, 300 Hz) through column A resulted in EMG responses whereas the same stimulation parameters when applied to column C did not evoke a significant EMG response. (E) Stimulation thresholds were orientation dependent and directional selectivity of motor side-effects was found at multiple depths as shown for 16 mm (left) and 20 mm (right).

**Fig. 5.** Example demonstrating how DBS-array VTA steering can correct for small lead misplacement. VTA distributions are overlaid to scale on an axial slice of the STN area from the Schaltenbrand-Wahren atlas. The VTA in steering mode is depicted by the red regions (20 mV AF threshold). The blue line represents the 20 mV threshold value for the symmetric stimulation mode. (A) The lead is situated in the middle of the anatomical target (STN) and a symmetric configuration is optimal in this case. (B) The DBS-array is displaced 1 mm lateral and 1 mm anterior with respect to the middle of the STN. The use of VTA steering enabled by the DBS-array enables to optionally cover the STN while spread to adjacent structures is kept to a minimum. By contrast, a symmetric (state-of-the-art) mode of identical stimulus amplitude (blue isoline) would stimulate adjacent structures yet sub-optimally cover STN, ZI, zona incerta; CI, capsula interna.
